■ **Goals of ADVID under climate change strategic line of research**

- To identify impacts of climate change in viticulture and needs of wine sector

- To promote studies to analyze evolution of climate conditions and evaluate the application of adaptation measures, in close collaboration with the wine sector and scientific partners at national and international level

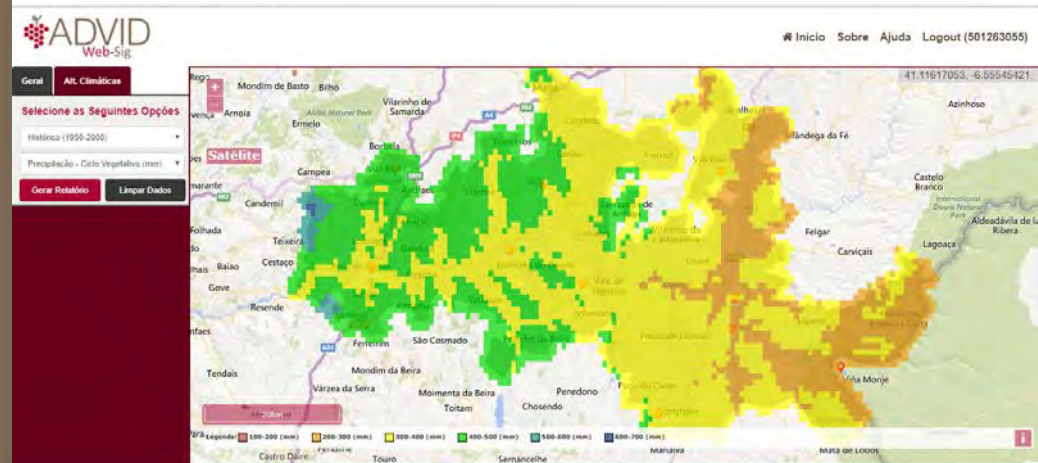

- To recommend to winegrowers the best management practices to reduce their vulnerability to climate change impacts, promoting the **stability of production, high quality of wines**, enhancing the **resilience of wine sector**

■ Study conducted in Douro about Climate projections (Jones 2012)

A climate assessment for the Douro wine region: an examination for the past, present and future climate conditions for wine production

ADVID developed a webtool that allow growers to have access to this information in order to support management decisions

■ A climate assessment for the Douro wine region - Study Description

- ✓ **11 climate parameters analyzed**
- ✓ **3 greenhouse gas emission scenarios (B2, A1B, A2)**
- ✓ **Spatial Climate: Historic Data (1950-2000)**
- ✓ **Three future time periods (2020, 2050, and 2080)**
- ✓ **Spatial Resolution: 1 km² (100 ha) .**

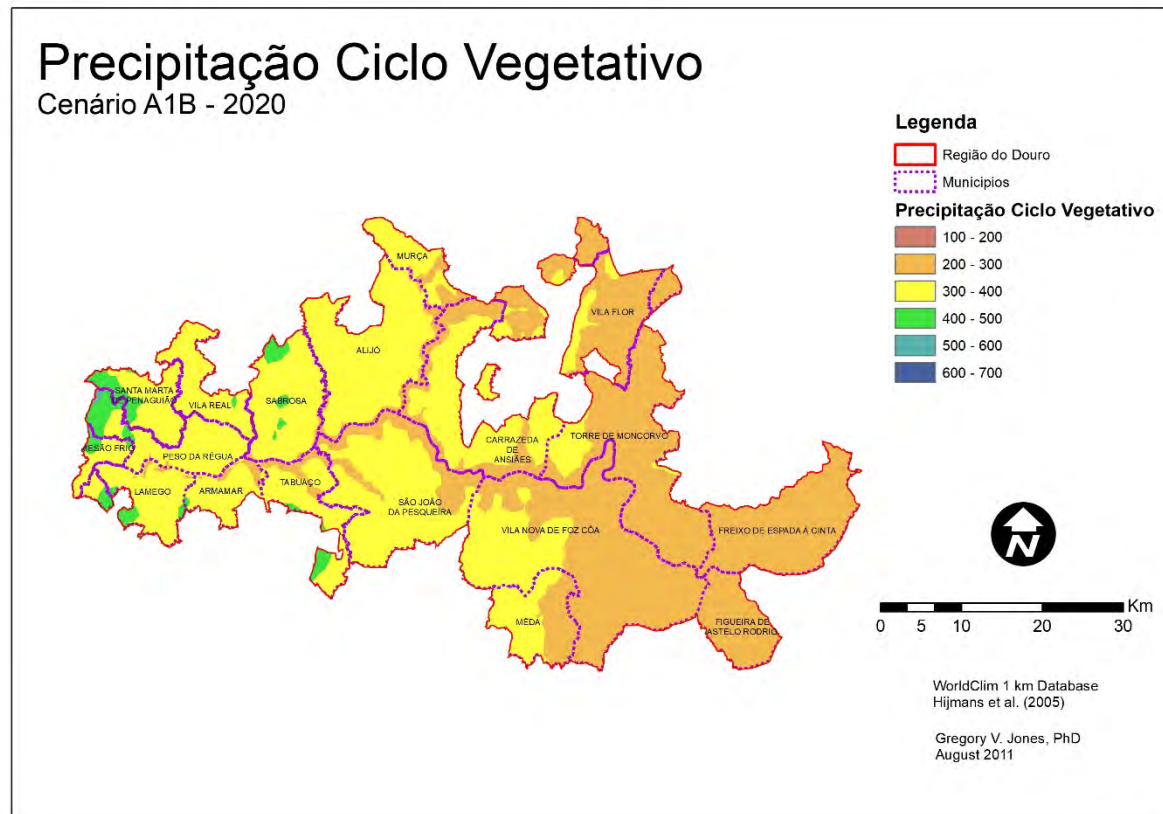

Climate Parameters
Annual Precipitation (mm)
Average Annual Temperature (°C)
Growing Season Active Temperatures (Σ TA, °C)
Growing Season precipitation(mm) – April to October
Growing Season Average temperature (°C) – April to October
Growing Season Maximum Temperature (°C) – April to October
Growing Season Minimum Temperature (°C) – April to October
Huglin Index
Winter Precipitation (mm) – November to March
Winter Maximum Temperature (°C) – November to March
Winter Minimum Temperature (°C) – November to March

- Future climate conditions in the Douro Wine Region were examined using IPCC SRES projections.

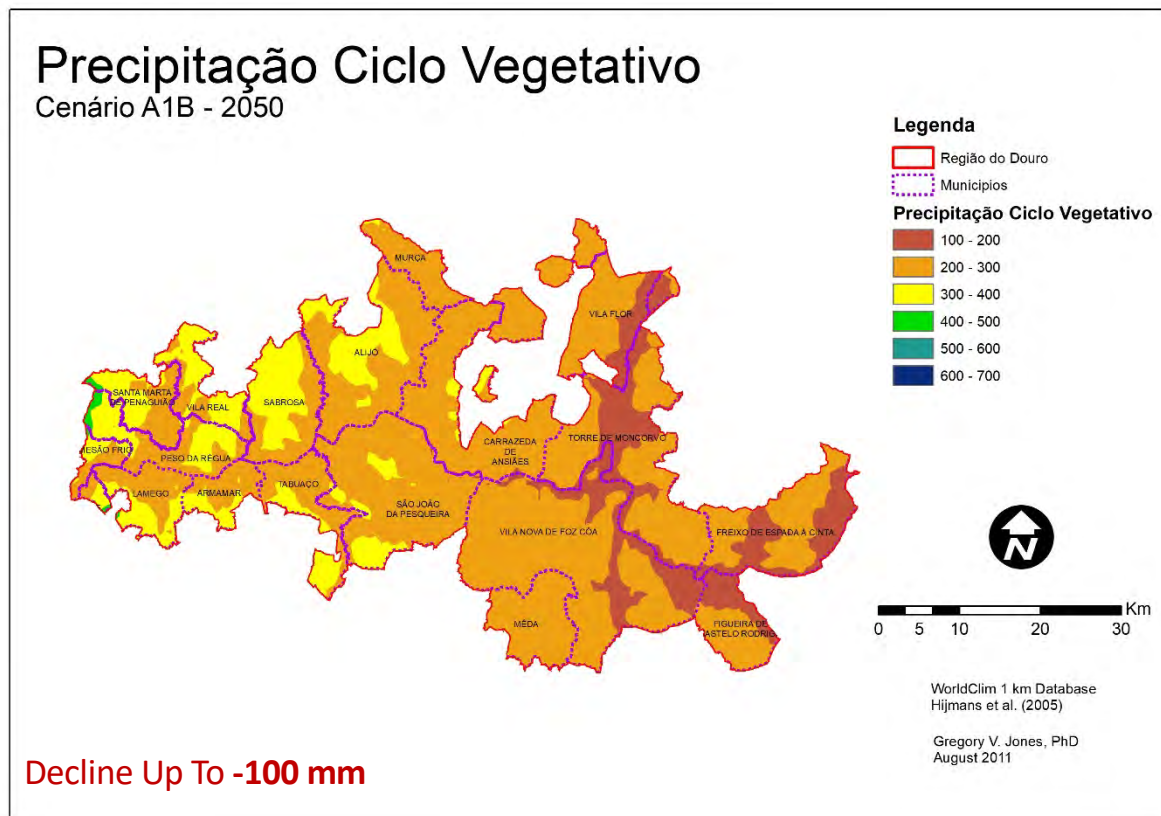

■ Growing Season precipitation (mm) - Historic (1950-2000)

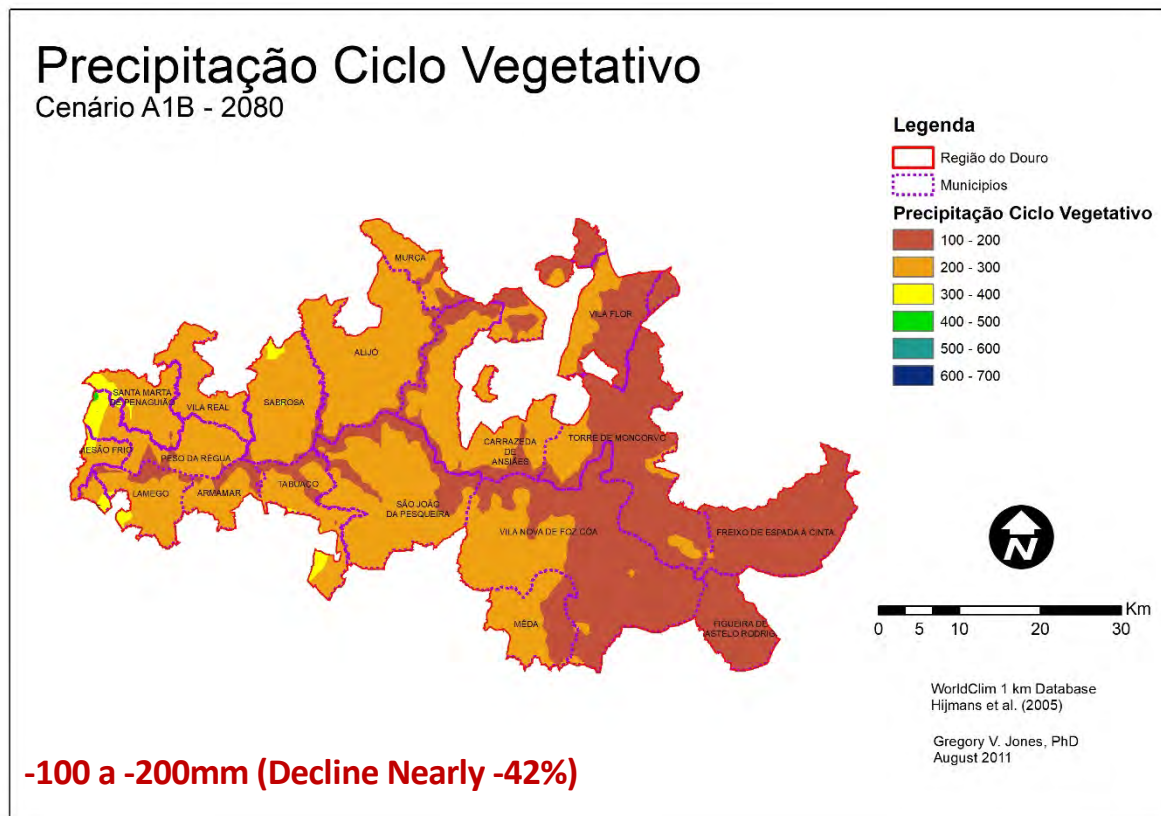

■ Growing Season precipitation (mm) - A1B Scenario 2020

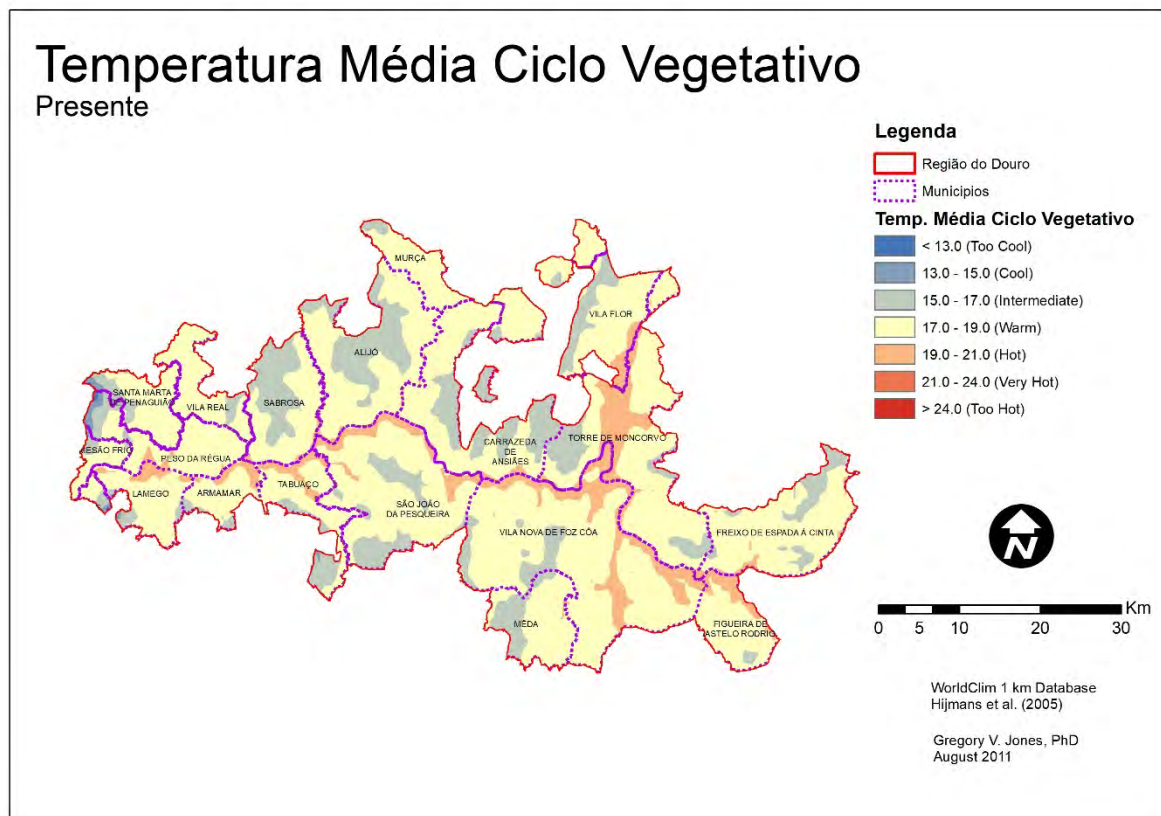

■ Growing Season precipitation (mm) - A1B Scenario 2050

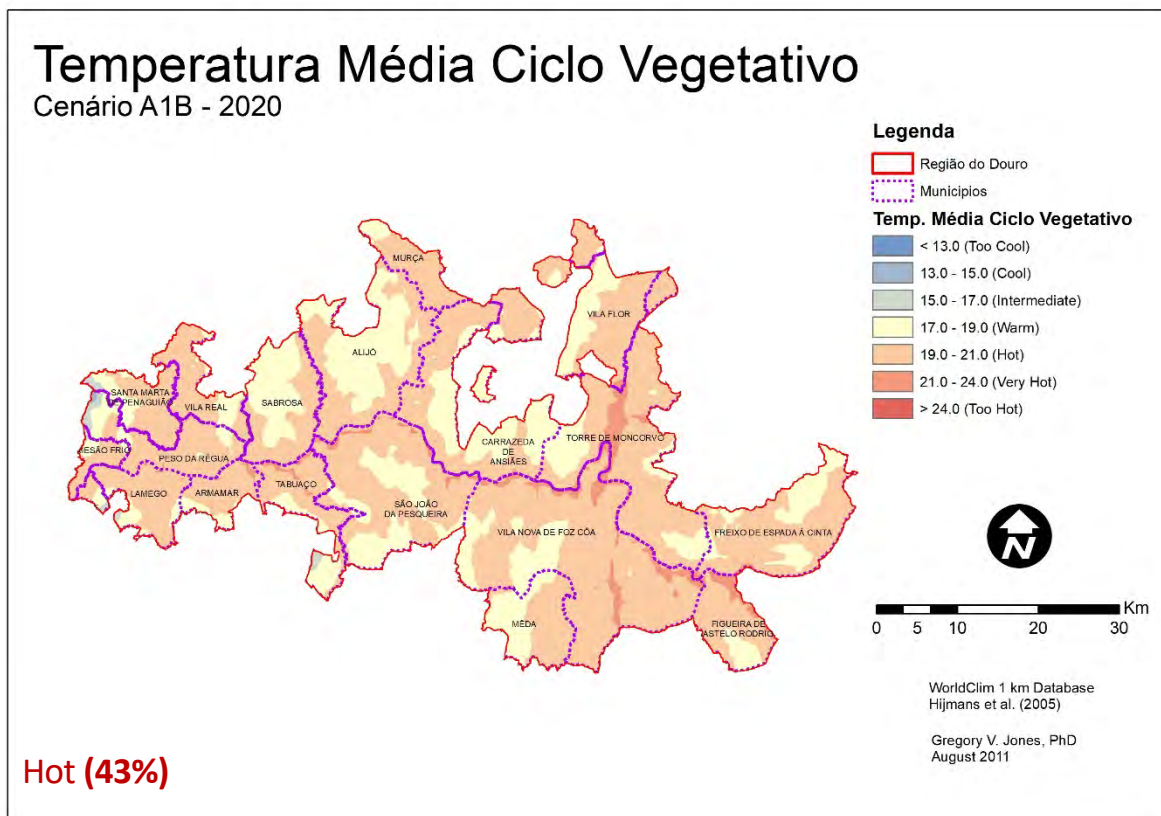

■ Growing Season precipitation (mm) - A1B Scenario 2080

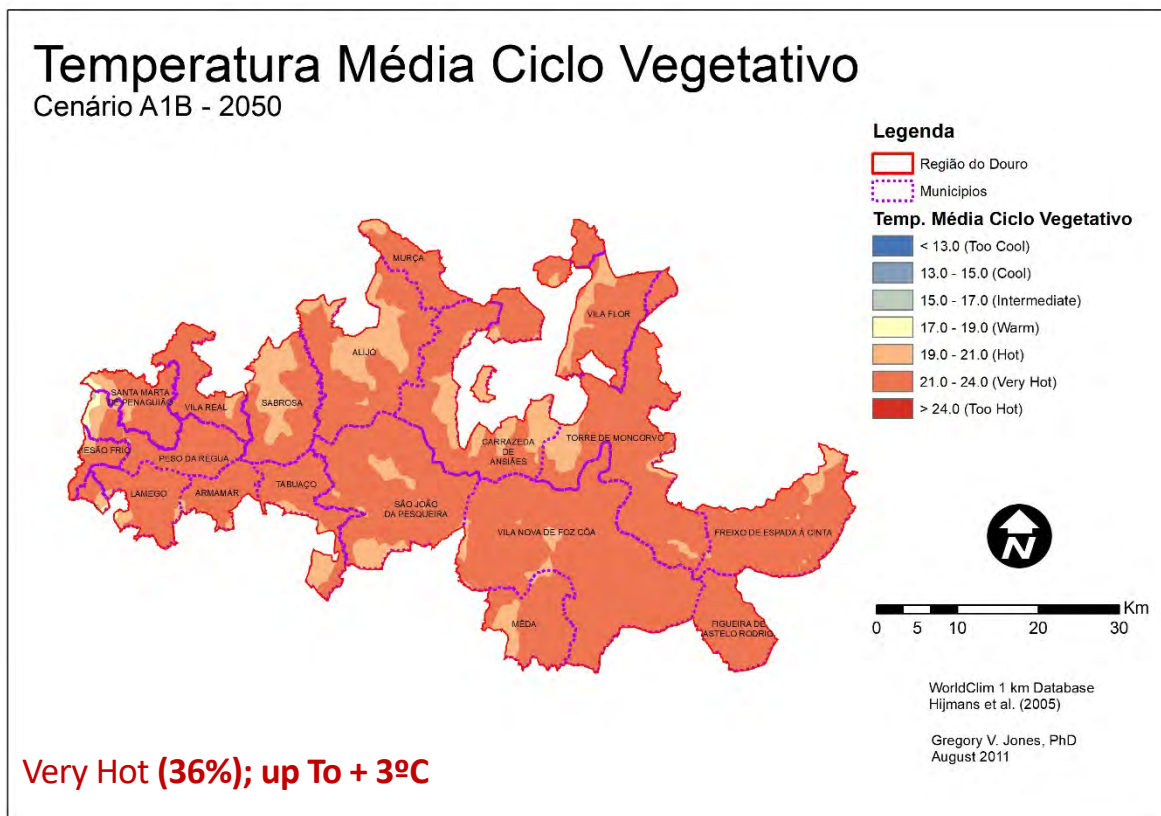

■ Growing Season Average temperature (°C) - Historic (1950-200)

■ Growing Season Average temperature (°C) - A1B Scenario 2020

■ Growing Season Average temperature (°C) - A1B Scenario 2050

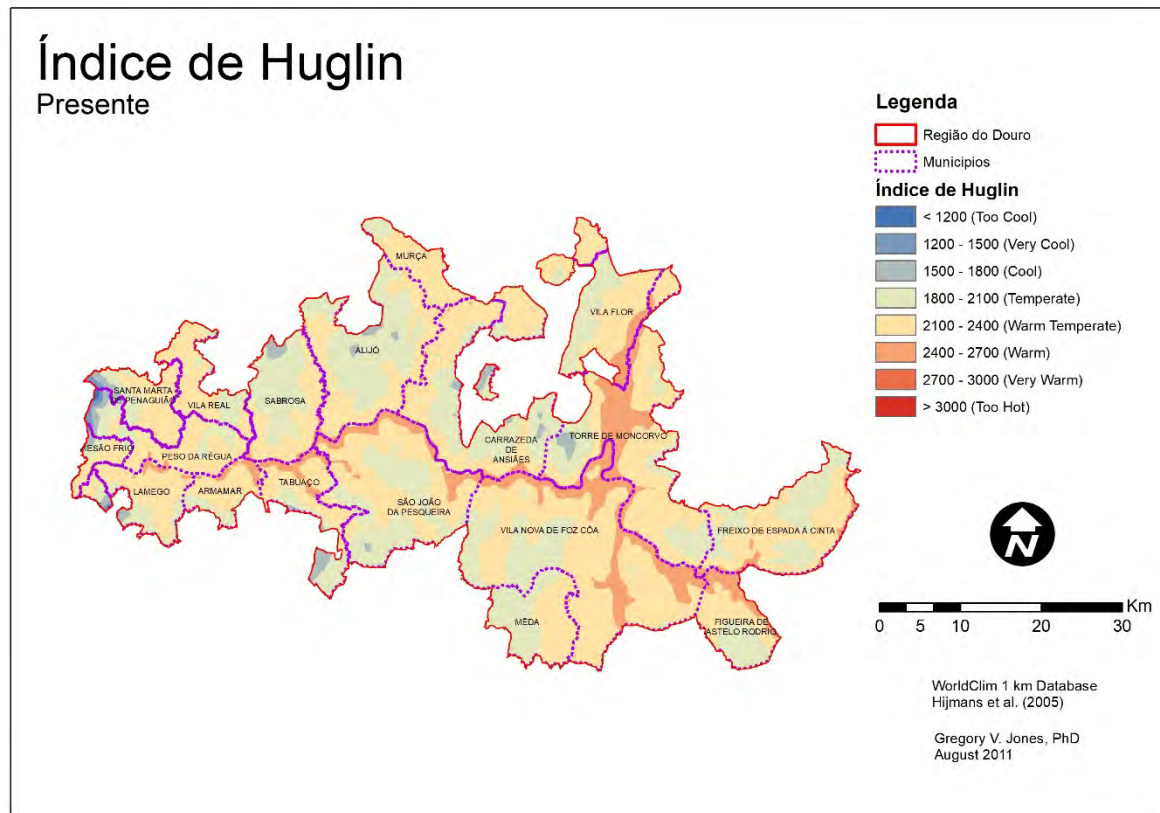

■ Growing Season Average temperature (°C) - A1B Scenario 2080

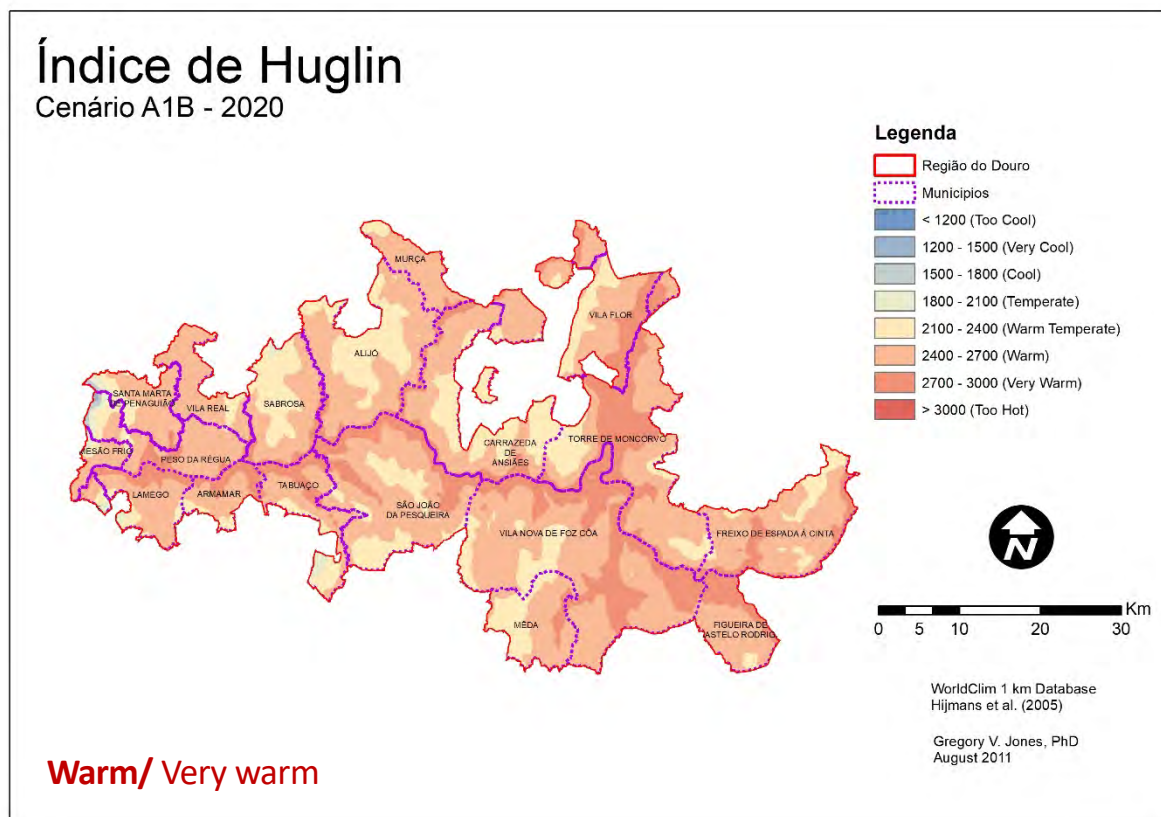

■ Huglin Index - Historic (1950-2000)

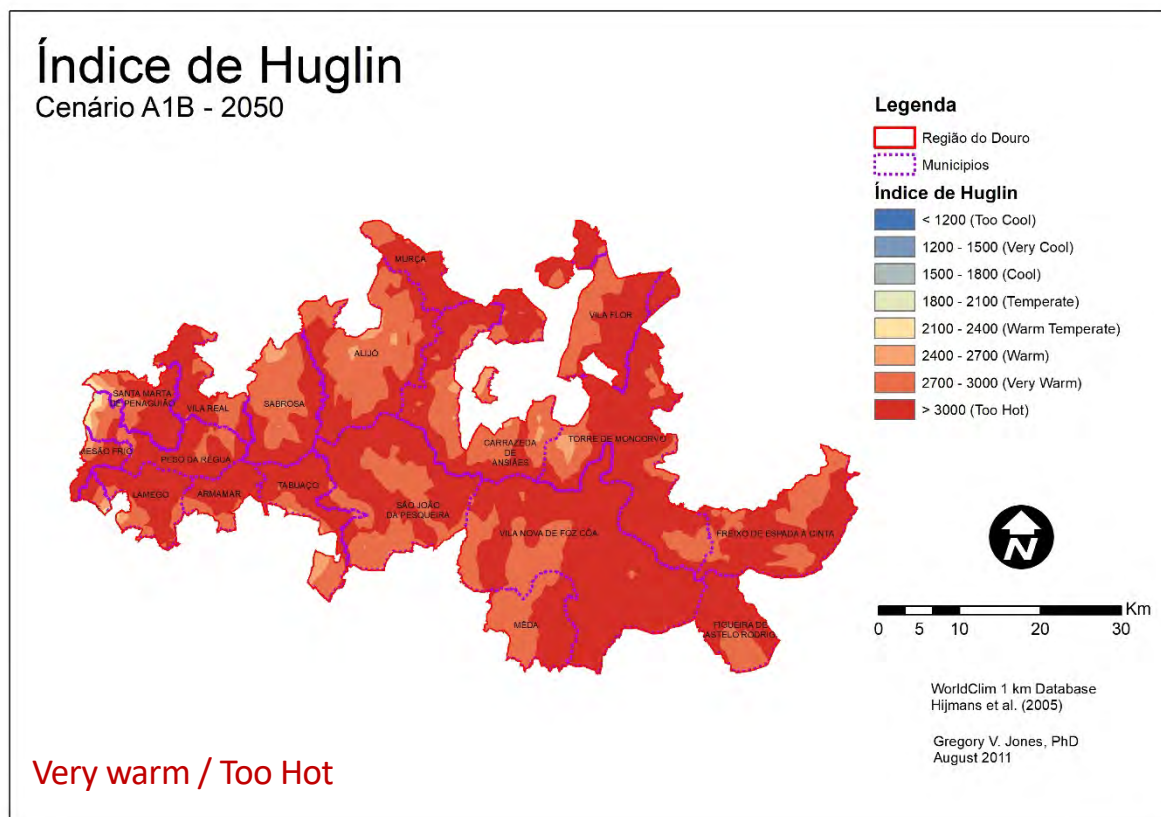

Bioclimatic Index used in viticulture that indicates suitability of an area for vine cultivation

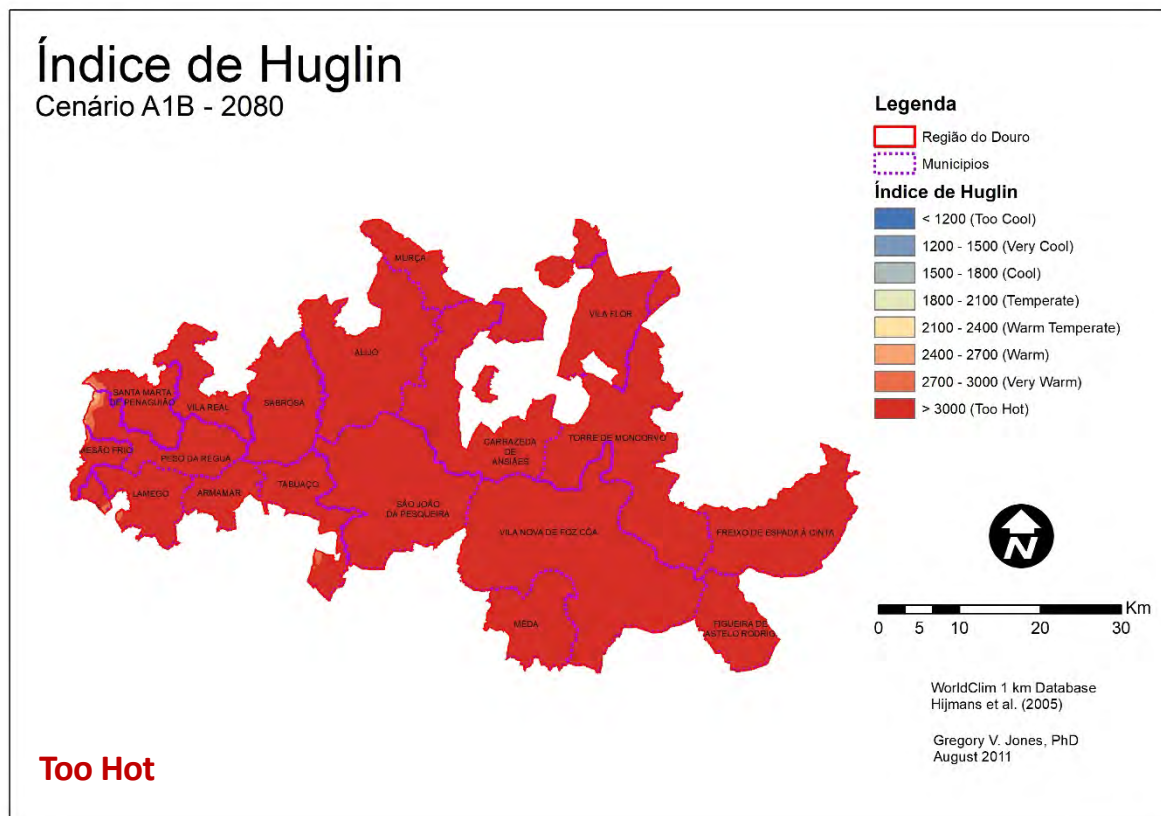

■ Huglin Index - A1B Cenário 2020

■ Huglin Index - A1B Cenário 2050

■ Huglin Index - A1B Cenário 2080

■ **Impacts (risks) of climate changes in viticulture**

- **Anticipation of grape ripening / Reduction in time window for harvest (ex. 2017)**
- **Changes in grape characteristics and wine profiles**
- **Physiological impacts** in vineyards (higher water, heat and radiative stresses)
- **Reduction in vineyards longevity**
- **Changes in pests and diseases complex** (ex. More trunk diseases, mealybugs, mites)
- **Impacts on soil quality (reduction in organic matter) with higher risk of erosion**
- **Lower productivity** with impacts on **economic sustainability**
- **Risk of abandonment of vineyards in drier zones**

■ Measures to be implemented on new vineyards

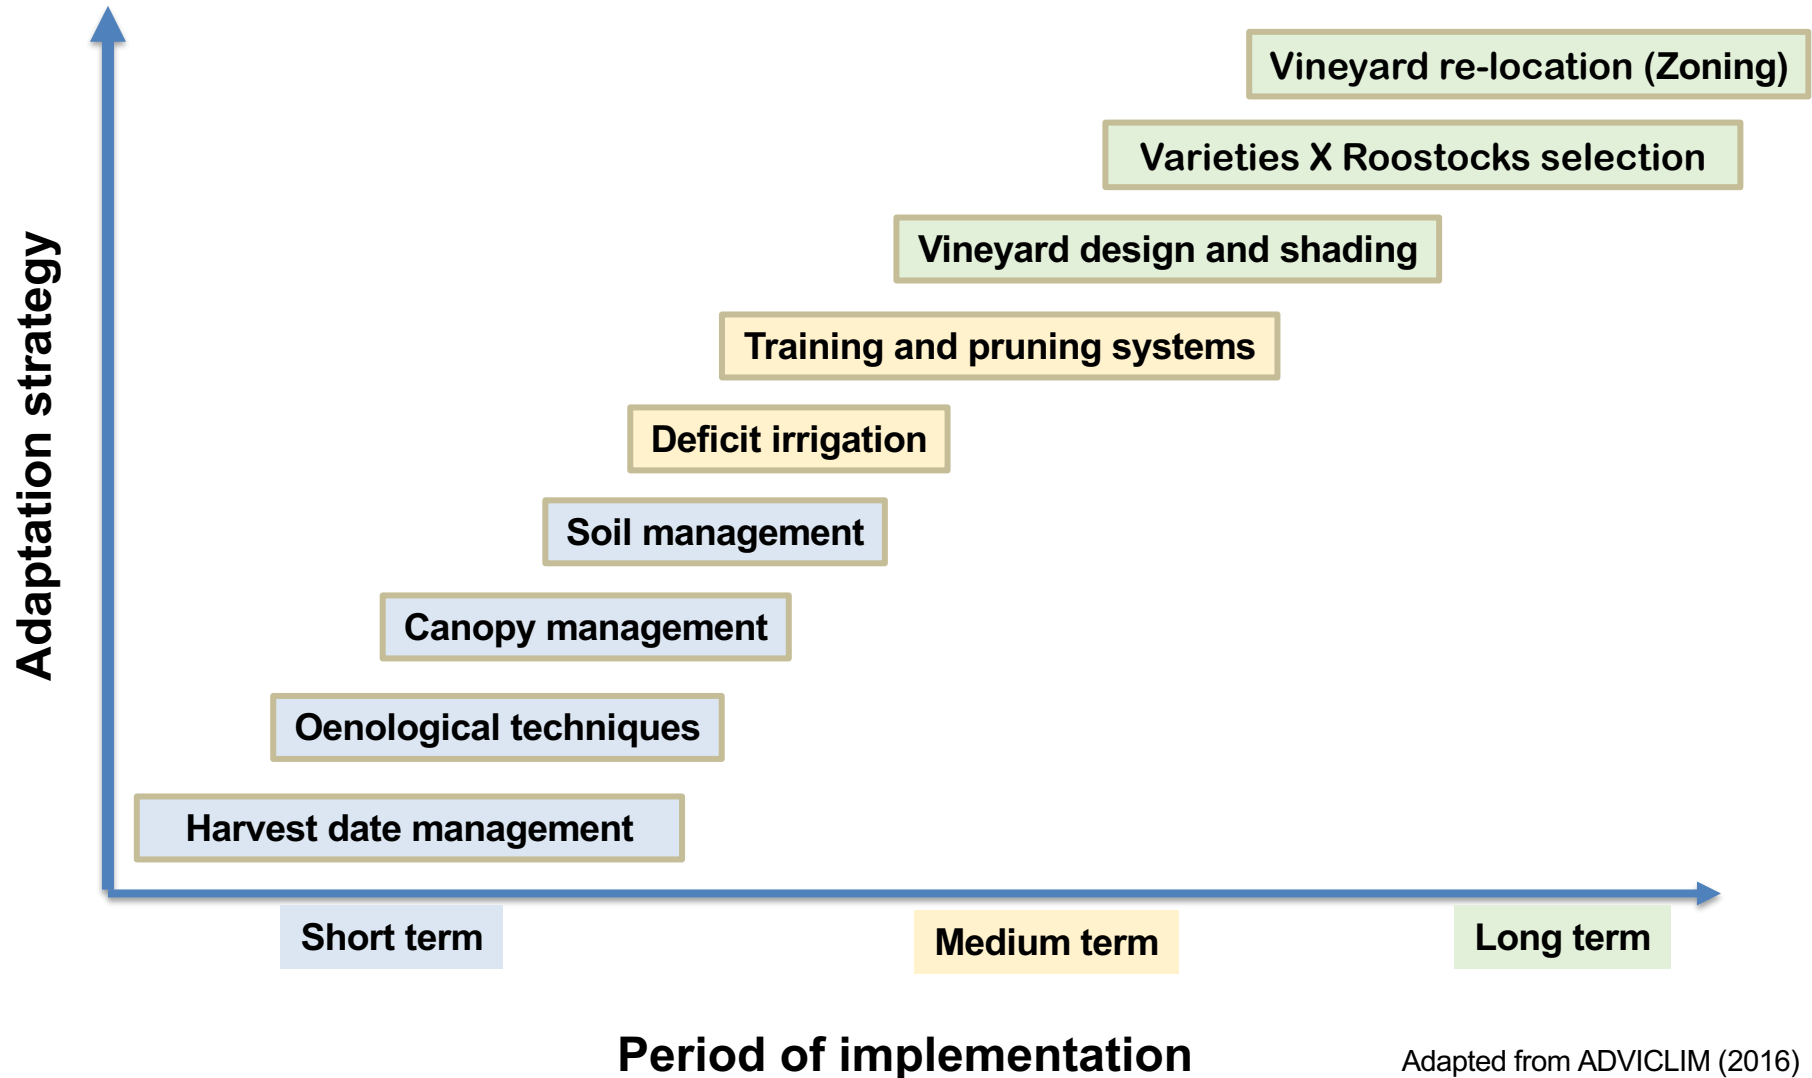

Avoiding unfavourable exposition (south) to prevent sun burn events

■ Water, heat and radiative stresses in August / September 2017

■ Adaptation measures to climate change and period of implementation

■ Adaptation measures to climate change under study in Douro Region

- a) Preservation and study of **genetic diversity** of Portuguese varieties
- b) **Application of kaolin** as a leaf protector against thermal and light stress
- c) Management of **Deficit Irrigation** (RD)
- d) Other studies ongoing (**application of biochar to soil; shadow nets; precision viticulture techniques**)

■ Genetic diversity in Portugal

Number of autochthonous varieties cultivated / km² in Europe
according to national official lists

■ Douro region – a genetic diversity reservoir

30 to 40 varieties in old vineyards

150 varieties located in the North of Portugal

- **Public-private association founded 2009 with the following goals:**
 - **Conservation of INTRAVARIETAL genetic variability in pots and field trials**
 - **Promote studies on growing and winemaking attributes of 200 autochthonous varieties**

Stop genetic loss of Portuguese varieties

The conservation park

Total area: 274 ha
Current vineyard: 30 ha

Total conservation area to be used: 110 ha
Already planted: 8 ha

10,54 ha

So far:

- $\approx 30\,000$ genotypes conserved in field trials
- over 16000 genotypes conserved at the experimental Pole of over 200 Portuguese native grape varieties (target: 50 000 genotypes)

■ Intervarietal diversity as a climate change adaptation measure

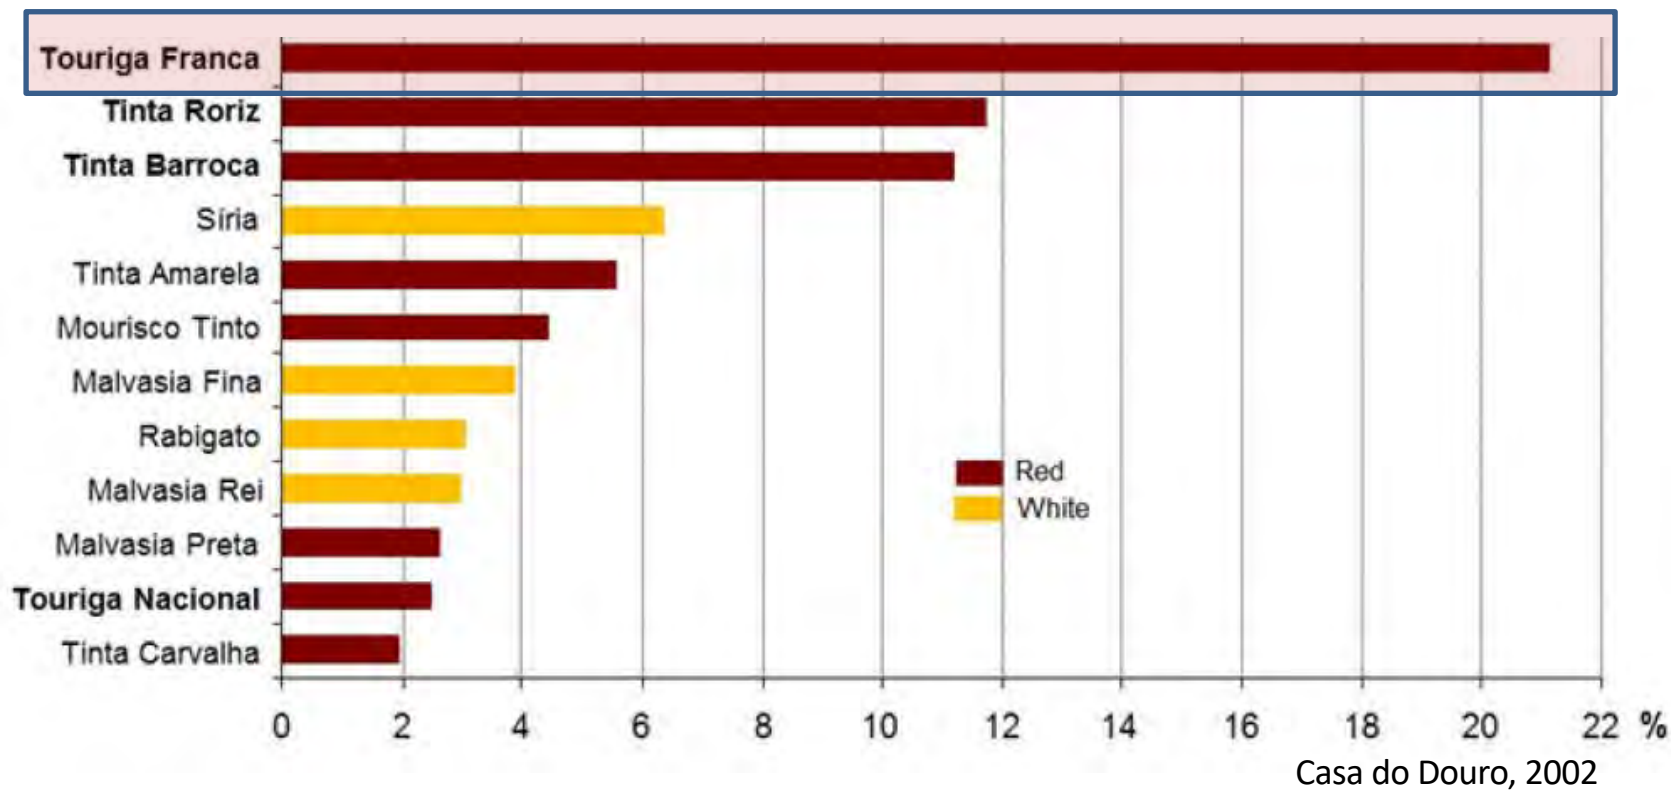

- Possibility to perform polyclonal selection, with different goals
- **Select varieties with higher stress resistance**

Ex: Tempranillo (*Tinta Roriz* in Douro) variety

- **30 selected genotypes with priority to anthocyanins** are now in a second cycle of comparison in 6 trials (4 in the Douro, 1 in Dão, 1 in Alentejo);
- Selection of **more heat tolerant genotypes** is ongoing in a trial in Alentejo

■ Most used varieties in Douro region

Touriga Franca, one of the most used variety, exhibit a higher resistance to climate impacts

Studies are going at Insituto superior de Agronomia (Lisbon) about its leaf anatomy

■ Classes of altitude in Douro region

Topographic and geographical conditions allow to relocate grape varieties (zoning)

SYMPINGTON FAMILY ESTATES

Heat requirements and length of phenological stages. Effects of rootstock on red grape varieties at Douro Region

Fernando ALVES¹, Afonso Edman², Jorge COSTA¹, Paulo COSTA¹, Paulo Macedo², Pedro Leal da Costa², Charles Symington³

¹ADVID (Associação para o Desenvolvimento do Vinho da Região do Douro) Quinta do Vale, 4170-000 Ourense, Portugal; ²Sympington Family Estates, Quinta do Vale, Portugal; ³Charles Symington & Partners, Quinta do Vale, Portugal

1. INTRODUCTION

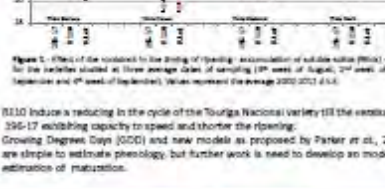

- Knowledge of the phenological stages development is crucial for the planning of the vineyard operations, and optimal timing of the ripening season is very important annual quality.
- Temperature is the major climate element for grapevine, several phenological stages.
- In the Douro, vines grow in climate conditions with important inter-annual and spatial variability.
- Rootstock is among the most important decisions to adapt varieties to a specific terroir.
- This work is an attempt to define climatological and thermal durations for some local red grape varieties and evaluate the potential contribution of different rootstocks on the phenological stages evolution growing in Douro Region.

2. MATERIALS AND METHODS

- The field experiment was located at Quinta do Vale (Sympington Family Estates).
- Altitude of 205m and it was planted in 1987 with moderate to severe (20%) facing north-east.
- Varieties Touriga Nacional (TN), Touriga Franca (TF) and Tinta Roriz (TR) was examined in the blocks grafted on the rootstocks R110, 196-17 and Superburgundy (S) and on the rootstock 1614.
- During 10 years (2002-2011) dates of the main phenological stages (bud break, flowering and veraison) were recorded, on average at 50% of their occurrence.
- Climate data: its from a weather station located at 3,2 km from the parcel and within 100m in altitude. GDD was calculated between each phenological stage.
- During ripening, samplings were taken on average at the 4th week of August, 2nd and 4th weeks of September.

3. RESULTS AND DISCUSSION

- In average the number of days to reach phenological stages are 82 (7.5% cv) (1st (an-bud break); 61 (11% cv) (bud break-flowering); and 54 (9% cv) (flowering-veraison).
- Coefficients of variation of the period Flowering-Veraison are the lowest for all varieties studied.
- Touriga Nacional has higher inter-annual variability of climatological durations and also exhibits a longer phase (bud break-veraison).
- R110 induces a shorter cycle mainly when compared with Superburgundy (S) and 1614.

EFFECTS OF THE ROOTSTOCKS AND ENVIRONMENT ON BEHAVIOUR OF THE cv TINTA RORIZ IN DOURO WINE REGION

Fernando Alves¹, Paulo Costa¹ and Nuno Magalhães²

¹ADVID - Associação para o Desenvolvimento do Vinho da Região do Douro, Quinta do Vale, 4170-000 Ourense, Portugal; ²Charles Symington & Partners, Quinta do Vale, Portugal

Introduction

The selection of the rootstocks needs to promote the better performance faced with a complex set of interactions, as soil type, physical and chemical properties, pests and diseases, water availability, grape variety and environmental factors. In order to give the stability and the better compromise between production and quality of the grafted grapevines cultivars.

The aim of this work is to examine the effects of different rootstocks and environmental conditions on yield and quality of the cv Tinta Roriz, the 2nd most planted grape variety in Douro Wine Region and the 10th all over the world (Tempranillo).

Material and methods

The trial was set up at Quinta do Vale (Vale do Douro), at an elevation of 200 m, north-facing, in two-row, terraces in a soil derived from schist, planted in 1988¹, (23 m x 1.3 m). The cv Tinta Roriz was grafted on Superburgundy (S), R110, 196-17, 1614, 1614P, 1614P, 196-17, 44-53 and 420A rootstocks and trained in double Royat with vertical shoot position. The climate for the years in study is characterized in Figure 2. The experimental design follows a model in randomized blocks, with three replications and 12 vines per rootstock type. At harvest yield components and grape quality were determined from 1987 to 2000.

Results and discussion

Table 1 - Effects of rootstock on yield and cluster weight per vine, berry weight, number of shoots per vine, weight of shoot (SD) and TSS content in Tinta Roriz. (Significant differences are indicated by different letters, P<0.05).

Year	Rootstock	Cluster weight (g)	Berry weight (g)	Number of shoots (n)	Weight of shoot (g)	TSS (%)

Introduction

Winegrape production in Mediterranean regions, especially in the Douro Demarcated Region (DDR, Northeast Portugal), is subject to warm and dry summer climate conditions, that may irreversibly impair some physiological processes, leading to poor grape yields and quality. Previous work by our team in the region clearly showed that grapevines growing under severe summer stress experienced significant decline in yield due to stomatal and mesophyll limitations to photosynthesis. Frequently, some of these leaves, particularly those lower on the canes and more directly exposed to sunlight, displayed irreversible photoinhibition and chlorosis followed by necrosis, unprotected the cluster zone and leading to a decrease in grapevine water use efficiency. Consequently, in low vigour vines, yield, berry weight and sugar concentration are significantly reduced. Furthermore, other berry characteristics, such as colour, flavour and aroma components are suppressed by excessive solar exposure of grapes and low water availability. Related with adaptation and mitigation practices, we wish to reinforce the knowledge of the effect of particle film applications, i.e. spraying canopies with a aqueous suspension of kaolin. Hence, the aim of the present study is to investigate the main effects of a foliar application with a kaolin particle film in the physiological behaviour of the "Touriga Nacional" variety.

Material and methods

Experimental trial: The experiment was undertaken in 2012 and 2013 in the commercial vineyard "Quinta do Vallado", located at Pêso da Régua in the DDR, northern Portugal.

Plant material: *Vitis vinifera* L. "Touriga Nacional", grafted onto 110 R. Three vineyard lines, located on a steep hill, with N-S orientated rows and with 20 plants each one, were pulverized soon after veraison, with 5% (w/v) kaolin (Surround WP, Engelhard Corp, Iselin, NJ). Three additional vineyard lines, with 20 plants each one, were maintained as control, i.e. without kaolin application.

Physiological and agronomical measurements: Leaf gas exchange rates were measured with an infrared gas analyser (LCA-3, ADC, England). Chlorophyll a fluorescence features were measured in situ with a pulse-amplitude-modulated fluorimeter (PAM 2, Hansatech Instruments, Norfolk, England). Total chlorophylls and total carotenoids were determined according to Lichtenhaler (1987). Chlorophyll concentration per area was also estimated non-destructively using a SPAD-502 meter (Minolta, Japan). Leaf temperature was measured with an infrared thermometer (Infratec KM800S, England) with a 15° field view. Leaf reflectance was measured from 200 to 1100 nm, using a leaf clip with a bifurcated fiber-optic cable attached to both HR2000 Spectrometer (Ocean Optics, Inc., Dunedin, USA) and to an Ocean Optics LS-1 tungsten halogen light source. At harvest, yield per vine was determined in 60 vines per treatment. Values were compared by a one-way ANOVA test. All means were compared at the 0.05 (*), 0.01 (**), and 0.001 (***) levels of significance.

Results

Discussion and conclusions

The application of 5% kaolin resulted in the formation of a whitish dry residue on the exposed leaves which increased the reflector capacity (Fig. 1). One of the direct effects of this application was a significant reduction of leaf temperature (Table 1). Consequently, during the summer period, the degradation of photosynthetic pigments was not as evident as in control ones (Table 2). Measurements of gas exchange indicate significantly higher A in kaolin leaves (Fig. 2). Particularly at ripeness stage, the increase in A was more evident than the slight increase in g, during warmer periods of the day, leading to higher A/g, and lower C/C_i. The increase of the photosynthetic rate in kaolin treated leaves was associated to an improvement of the PSII photochemical efficiency. At harvest, mainly in 2012, the kaolin effect had a clearly positive impact on the productivity performance of the vines (Table 4). In conclusion, the results of this study, carried out with grapevines of the same variety and under similar field-grown conditions, emphasized the beneficial role of kaolin as a short-term measure for growing grapevines under high irradiance levels and heat/water stress conditions, such as in Douro region. Particularly during the ripening stage, the photosynthetic capacity depression was associated with important photochemical and biochemical changes that can negatively compromise the grape production, particularly emphasized in low yield years.

Deficit irrigation allow to regulate the production at **reasonable levels (1,5 to 2,5 kg/plant)**

■ Analyses of grape quality (2014 - 2019)

Tanins

Antocianins

The two modalities of Deficit Irrigation **did not result in negative impacts** in Antocianins and Tannins

■ In available places, install water reservoirs

As precipitation will be concentrated during winter, it is important to save as most as possible water from rain to be used on summer for irrigate vineyards

■ Ongoing studies- Application of “BIOCHAR” to vineyard soil

BIOCHAR- charcoal produced from plant matter that can be applied to soil to improve its characteristics

▪ Ongoing studies- Application of “shading nets”

to reduce radiative and heat stresses

■ Work ongoing related with precision viticulture

- **Project WINESPECTRA - Management of deficit irrigation in vineyards based on vegetation indexes**

- **Partnership:** Sciences faculty of University of Porto, ADVID, Real Companhia Velha and Symington Family Estates

Evaluate the potential of vegetation indexes based on reflectance data, to estimate water status of vineyards

- **Project VINIOT - Network-based precision viticulture service IoT sensors for digital transformation of SMEs in the SUDOE space**

- **Partners:** AIMEN, AGACAL, ADVID, IFV, INRA, AGAMELARIOJA, FEUGA, IRSTEA

Creation of a new technology monitoring service for vineyards in real time, to assess relevant parameters in viticulture such as water status, grape maturity or pest and phytosanitary status

▪ General conclusions

- There are several adaptation measures to climate change
- The adaptation measures should not be applied in a general way, but **validated** in different terroirs, years and different production objectives (ideally by each wine company)
- Serious and long-term studies are needed to allow us to correctly **diagnose the problem** and consequently **define the most appropriate solutions**
- Those studies should result in **guidelines that allow the recommendation of most effective adaptation measures** to reduce viticulture's vulnerability to climate change

**Thanks for your attention
Obrigada!**
